## 1. Tracing

**(5 Points)**

Implement a simple class with at least one data field and two methods; one of these methods is to be called by the other one. In the test program create an object of this class, and call the methods and access the data fields.

Furthermore, implement an aspect *Tracing* that protocols each method call as well as each access to one of the data fields. Please distinguish between the regular ending of a method and its abortion by an exception. The so generated output could for example look like this:

```
Entering addPositiveValue
Accessing last
Accessed last
Entering setPositiveValue
Accessing positiveValues
Accessed positiveValues
Exiting setPositiveValue
Accessing last
Accessed last
Accessing last
Accessed last
Exiting addPositiveValue
Entering setPositiveValue
Exiting setPositiveValue ERROR: value is not positive (java.lang.IllegalArgumentException)
Exiting addPositiveValue ERROR: value is not positive (java.lang.IllegalArgumentException)
```

As we now want to indent outputs according to their interlacing in order to increase the lucidity of the outputs, implement indentation without changing the original *Tracing* aspect.

## 2. Caching

**(5 Points)**

Develop a class *BinomialCoefficient* that offers the static method *Calculate* for calculating the binomial coefficient. This calculation is defined as follows:

$$bc(n,0) = 1$$

$$bc(n,n) = 1$$

$$bc(n,m) = bc(n-1,m-1) + bc(n-1,m)$$

Implement an aspect *LogRecursiveCalls* that counts the number of recursive method calls and writes it to the console as soon as the execution of the first call of *Calculate* is finished.

Furthermore, implement another aspect *BinomialCache* that caches calculated (intermediate) results and calls *Calculate* only if the required result is not known yet.

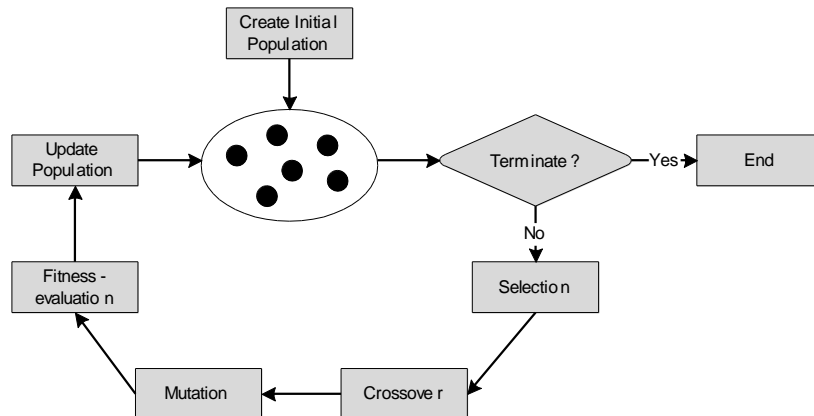

Finally, add an aspect *RuntimeMeasurement* that can be used for measuring and displaying the runtime consumed by a method.

Test all aspects extensively and document, whether the use of *BinomialCache* is reasonable or not.

### 3. Aspect-Oriented TSP Solver

(3 + 3 + 2 + 6 Points)

On elearning you can find a simple program *TSPSolver* that solves the traveling salesman problem (TSP) with genetic algorithms (GAs). GAs are evolutionary algorithms that simulate natural evolution using the adaption of species as optimization technique. The basic workflow of a GA looks like this:

A standard GA with tournament selection (tournament group size  $k = 2$ ), order crossover, inversion mutation and generational replacement is already implemented. Path encoding is used for representing solution candidates, i.e., each roundtrip is encoded as a permutation; e.g., [1 3 2 5 4] represents the roundtrip from city 1 to 3 to ... to 4 and back to city 1.

Furthermore, we here already have several aspects that modify the behavior of the program: The aspect *MeasureRuntime* is used for measuring the runtime of an execution of the algorithm, the aspect *RandomSelection* replaces the originally used tournament selection, and the aspects *CyclicCrossover* and *MaximalPreservativeCrossover* replace the respective originally used crossover operator.

Thus, we here see that aspect oriented programming is ideal to enhance (and hopefully improve) the *TSPSolver* with new concepts. Your task is now to implement the following additional aspects for *TSPSolver*:

- Implement an aspect *CountEvaluatedSolutions* that calculates the number of evaluated solutions and eventually writes it to the console as soon as the algorithm has terminated. Based on this implement another aspect *LimitEvaluatedSolutions* that ensures that no next iteration of the algorithm is executed as soon as a predefined maximum number of evaluations is reached.
- Develop an aspect *Elitism* that adds 1-elitism to the already implemented replacement strategy (generational replacement). I.e., at each generation step the best individual of the parents generation survives and replaces the worst of the new children. Using this aspect we get a monotonous improvement of the quality of the population's best individual.
- Add an aspect *ProtocolProgress* to *TSPSolver* that stores best, worst and average qualities of the population and writes it to the console after the algorithm has finished.
- Unfortunately *TSPSolver* does not have any graphical visualization. Since we already have a framework for generating SVGs, your final task is now to use this framework for plotting the progress of the best, average and worst quality as well as the best roundtrip found by the algorithm.

# 1 Tracing

Dieser Abschnitt beschäftigt sich mit der Dokumentation der Aufgabenstellung *Tracing*.

## 1.1 Lösungsidee

Für das Testen des *Tracings* wurde die Klasse *application.PositiveValueStore* implementiert, die mehrere verschachtelte Aufrufe sowie das Auslösen einer Ausnahme implementiert. Die Klasse *application.Main* wurde von den Aspekten ausgenommen, damit die implementierten Testmethoden nicht in den *Logs* aufscheinen.

Der Aspekt *TracingAspect logged* alle Aufrufe von Konstruktoren, Methoden und Zugriffe auf *Properties* von Klassen und zwar vor und nach dem Aufruf. Es wurden die *PointCuts methodCall*, *fieldAccess*, *newObject* implementiert, für welche die *before*, *after* *Advices* definiert wurden. Die *Advices loggen* die Zugriffe, wobei die *Logs* immer mit den Wörtern '[Before|After]' beginnt.

Der Aspekt *IndentationLogTrace* implementiert das Einrücken der *Logs*, um die Schachtelung der Methodenaufrufe zu verdeutlichen. Es wird ein *PointCut* auf alle Methoden der Schnittstelle *org.slf4j.Logger* definiert und ein *around Advice* implementiert, der den übergebenen Text formatiert, je nachdem ob die erwartende Zeichenkette ([Before|After]) am Anfang des Textes gefunden wurde. Wird eine solche Zeichenkette am Anfang des Textes gefunden, wird bei *Before* eine definierte Anzahl von Leerzeichen am Anfang des Textes eingefügt und beim Finden des Textes *After* einmalig die definierte Anzahl von Leerzeichen am Anfang des Textes entfernt.

## 1.2 Quelltexte

Folgender Abschnitt enthält die implementierten Klassen, Aspekte und das implementierte Testprogramm.

Listing 1: PositiveValueStore.java

```
1 package application;
2
3 /**
4  * This class represents a positive value store
5  *
6  * @author Thomas Herzog <herzog.thomas81@gmail.com>
7  * @since 05/05/17
8  */
9 public class PositiveValueStore {
10
11     private int[] positiveValues;
12     private int size;
13     private int last = 0;
14
15     public PositiveValueStore(int size) {
16         this.positiveValues = new int[size];
17         this.size = size;
18     }
19

## 2 Caching

Dieser Abschnitt beschäftigt sich mit der Dokumentation der Aufgabenstellung *Caching*.

### 2.1 Lösungsidee

Der Algorithmus für die Berechnung des Binomialkoeffizienten wird in der Klasse *BinomialCoefficient* als statische Methode *calculate* implementiert.

Es wird ein abstrakter Aspekt *AbstractAspect* implementiert, der die *Pointcut firstCall*, *allCallsWithArgs* und *innerCalls* definiert, sowie *before*, *after* *Advices* für *firstCall* definiert, die vordefinierte implementierte Methoden aufrufen, die von den abgeleiteten Aspekten überschrieben werden können. Dies wird so strukturiert, damit alle Aspekte auf den ersten Aufruf der Berechnungsmethode reagieren können, um ihre Zustände zu initialisieren und zurückzusetzen. Dazu werden zwei Methoden *beforeFirstCall* und *afterFirstCall* zur Verfügung gestellt, die von den konkreten Aspekten überschrieben werden können. Die Methoden *beforeFirstCall* und *afterFirstCall* sind mit leeren Methodenrumpf in der Klasse *AbstractAspect* implementiert.

Es wird der Aspekt *LogRecursiveCallsAspect* implementiert, der einen *after Advice* definiert, der nur dann ausgeführt wird wenn die boolesche Variable *Main.LoggingEnabled* auf den Wert *true* gesetzt ist und die Bedingungen definiert im *PointCut innerCalls()* erfüllt sind. Beim ersten Aufruf der Berechnungsmethode wird vor dem Aufruf der Methode der Zähler initialisiert und nach dem Aufruf das Resultat über den *Logger* in die *Logs* geschrieben und der Zähler zurückgesetzt.

Es wird der Aspekt *BinomialCacheAspect* implementiert, der einen *around Advice* definiert, der nur ausgeführt wird wenn die boolesche Variable *Main.CachingEnabled* auf den Wert *true* gesetzt ist und die Bedingungen definiert im *PointCut allCallsWithArgs(n,m)* erfüllt sind. Der *around Advice* speichert die Berechnungsergebnisse, um sie bei einem erneuten Auftreten der Variablen *n*, *m* zurückzuliefern, um so einen weiteren rekursiven Abstiegt zu verhindern. Beim ersten Aufruf der Berechnungsmethode wird vor dem Aufruf der Methode der *Cache* initialisiert und nach dem Aufruf der *Cache* geleert. Es wird die Klasse *BinomMapKey* implementiert, die als Schlüssel in einer *java.util.HashMap* fungiert, welche die berechneten Werte speichert.

Es wird der Aspekt *RuntimeMeasurementAspect* implementiert, der die Dauer der gesamten Berechnung misst und über den *Logger* in die *Logs* schreibt. Dieser Aspekt überschreibt die beiden Methoden *beforeFirstCall* und *afterFirstCall*, die von der abgeleiteten Klasse *AbstractAspect* zur Verfügung gestellt werden. Dieser Aspekt wird nur dann ausgeführt, wenn die boolesche Variable *Main.RuntimeMeasurementEnabled* auf den Wert *true* gesetzt ist

### 2.2 Quelltexte

Folgender Abschnitt enthält die implementierten Klassen, Aspekte und das implementierte Testprogramm.

## 2.3 Tests

Folgender Abschnitt enthält die Tests der Aufgabenstellung in Form der generierten *logs*.

Während der Tests hat sich gezeigt, dass mit aktiviertem *Caching* sich das Laufzeitverhalten deutlich verbessert hat, da die rekursiven Aufrufe deutlich weniger geworden sind und daher auch die Anzahl der Berechnungen sich deutlich verringert hat.

### 3 Asepct-Oriented TSP Solver

Dieser Abschnitt beschäftigt sich mit der Dokumentation der Aufgabenstellung *Asepct-Oriented TSP Solver*.

#### 3.1 Lösungsidee

Die Projektstruktur wurde dahingehend verändert, dass die Schnittstellen und die *Exceptions* in eigene Pakete ausgelagert wurden. Die Konfiguration der Aspekte wurde in der Klasse *util.AspectjConfig* zusammengeführt, die jetzt alle booleschen Variablen enthält die von den Aspekten verwendet werden, um zu entscheiden, ob sie aktiviert sind oder nicht. Die nötigen Änderungen in den bestehenden Aspekten wurden vorgenommen, damit die Aspekte mit der geänderten Projektkonfiguration arbeiten können.

Es wird der Aspekt *CountEvaluatedSolutionsAspect* implementiert, der die Anzahl der evaluierten Lösungen zählt. Es wird ein *PointCut executeCall* definiert, für den die beiden *before*, *after Advices* definiert werden, wobei der *before Advice* vor dem Methodenaufruf der Methode *Algorithm.execute* den Zähler initialisiert der *after Advice* nach dem Methodenaufruf der Methode *Algorithm.execute* das Resultat über einen *Logger* in die *Logs* schreibt und den Zähler zurücksetzt. Ein weiterer *after Advice* erhöht den Zähler nach dem Methodenaufruf der Methode *Solution.evaluate*. Dieser Aspekt arbeitet nur gegen die Schnittstellen *Algorithm* und *Solution* und ist daher auf alle Implementierungen dieser Schnittstellen anwendbar. Dieser Aspekt wird als abstrakt ausgewiesen, da der zu implementierende Aspekt *LimitEvaluatedSolutions*, von diesem Aspekt ableiten soll. Dieser Aspekt greift nur wenn die boolesche Variable *AspectjConfig.countSolutionsEnabled* auf den Wert *true* gesetzt ist.

Es wird der Aspekt *GAElitismAspect* implementiert, der die schlechteste Lösung der neu erstellten Kinder durch die beste Lösung des vorherigen Durchlaufs ersetzt. Es wird ein *around Advice* für die Methode *GA.createChildren* implementiert, der das zurückgelieferte *Array* der Kinder manipuliert. Wird ein Kind ausgetauscht, so wird eine Meldung über einen *Logger* in die *Logs* geschrieben. Dieser Aspekt ist abhängig von der Klasse *GA*, da die Schnittstelle *Algorithm* die Methode *createChildren* nicht definiert. Dieser Aspekt greift nur wenn die boolesche Variable *AspectjConfig.elitismEnabled* auf den Wert *true* gesetzt ist.

Es wird der Aspekt *LimitEvaluatedSolutions* implementiert, der die Iteration beim Erreichen einer vorgegebenen Anzahl von evaluierten Lösungen abbricht. Es wird hierbei das Ausführen der nächsten Iteration verhindert, wodurch in der aktuellen Iteration trotzdem mehr als die vorgegebenen Lösungen evaluiert werden können, daher muss die vorgegebene Anzahl der Iterationen ein Vielfaches der evaluierten Lösungen/Iteration sein, damit genau bei der vorgegebenen Anzahl abgebrochen wird. Dieser Aspekt erbt von dem implementierten abstrakten Aspekt *CountEvaluatedSolutionsAspect* und verwendet dessen Zähler. Ein *around advice* für die Methode *Algorithm.iterate* verhindert das Ausführen der Iteration und setzt eine boolesche Variable auf *true*, die beim *around advice* für die Methode *Algorithm.isTerminated* *true* als Resultat liefert, wenn die Iteration abgebrochen werden soll. Dieser Aspekt ist anwendbar auf alle Implementierungen der Schnittstelle *Algorithm*.

Es wird der Aspekt *GAProtocolProgressAspect* implementiert, der die beste Lösung, schlechteste Lösung und den Durchschnitt der Lösungen einer Population einer Iteration speichert und nach dem Ausführen des Algorithmus über einen *Logger* in die *Logs* schreibt und ein SVG-Diagramm mit der Bibliothek *gp2.svg-generator* erstellt. Zusätzlich wird ein SVG-Diagramm mit dem besten *roundtrip*, der besten Lösung, die vom Algorithmus gefunden wurde erstellt. Es wird der *PointCut firstExecuteCall* definiert, für den die beiden *before*, *after Advices* definiert werden, wobei der *before Advice* die Zustände des Aspekts initialisiert und der *after Advice* die Zustände des Aspekts zurücksetzt. Es werden zwei *after Advices* definiert, wobei ein *after Advice* nach der Ausführung der Methode *Algorithm.initialize*

## Übung 3

und der andere *after Advice* nach der Ausführung der Methode *Algorithm.iterate* ausgeführt werden. Der *after Advice* für die Methode *Algorithm.initialize* ist notwendig, weil dort die erste Population erstellt wird. Dieser Aspekt greift nur wenn die Variable *AspectjConfig.reportAlgorithmEnabled* auf den Wert *true* gesetzt ist.

Es wird eine Klasse *AspectReport* implementiert, welche die gesammelten Daten über einen *Logger* in die *Logs* schreibt, ein SVG-Diagramm für *best*, *worst*, *average* erstellt und ein SVG-Diagramm für den besten *roundtrip* der besten vom Algorithmus gefundenen Lösung erstellt. Um das SVG-Diagramm zu zeichnen, wurde der in der vorherigen Übung implementierte SVG-Generator verwendet. Da in der letzten Übung kein *PolylineShape* implementiert wurde, wird der Verlauf mit einem *LineShape* gezeichnet, wobei die *Destination* der vorherigen Iteration als *Origin* der aktuellen Iteration verwendet wird. Eine *Polyline* wäre zwar effizienter und das SVG-Dokument würde weitaus kleiner ausfallen, jedoch stand mir kein implementiertes *PolylineShape* zur Verfügung.

## 3.2 Quelltexte
